Project Application to Object-Oriented Principles analysis

Classes and Objects

In the CLI menu project, the GamingConsole class acts as a template for the objects that will represent the game consoles. The class defines the attributes and methods related to the console, such as the specification, storage options, and more.

Encapsulation

The GamingConsole class encapsulates the internal details of the console specifications and functionality. Public methods such as `display_specs()`, `storage_options()`, and `compatibility()` provide an interface for interacting with the console without exposing the internal details.

Inheritance

In the code provided, inheritance is used through the abstract class GamingConsole. Concrete subclasses (implementations) must provide specific implementations for the abstract methods defined in the base GamingConsole class.

Polymorphism

Polymorphism manifests itself in the CLI menu when methods of the GamingConsole class are invoked. Depending on the option selected in the menu, a different method is executed, but all methods belong to the same interface (the GamingConsole class).

Abstraction

The GamingConsole class provides an abstraction of a gaming console, allowing the user to interact with it through methods such as `display_specs()` without needing to understand the internal implementation of how this data is handled.

Example Implementation in Code

Here is how these concepts are implemented in the code of the project:

GamingConsole class defines the structure and behavior of the gaming console.

Methods such as `display_specs()` and `storage_options()`: Provide an interface to interact with the console objects without exposing the internal logic.

User Interface in `menu.py`: Uses polymorphism to call different methods according to the user's choice.
